### Optimizing control concept

• A main concept regarding advanced control is that of **finding an optimal performance according to a specified objective**, subject to the system variable limits.

### Optimizing control concept

- A main concept regarding advanced control is that of **finding an optimal performance according to a specified objective**, subject to the system variable limits.
- 1: Define a control objective. What the controller should do: steering the system quickly to a given point or set; steering the system to a given point or set using the less control effort; minimizing an economic cost function in both, the path and the final point or set, etc.

### Optimizing control concept

- A main concept regarding advanced control is that of **finding an optimal performance according to a specified objective**, subject to the system variable limits.
- 1: Define a control objective. What the controller should do: steering the system quickly to a given point or set; steering the system to a given point or set using the less control effort; minimizing an economic cost function in both, the path and the final point or set, etc.
- 2: Model and Constraints. Consider the possibilities that the system gives us to be controlled: we need a dynamic model, which includes limits for the variable as a part of the system description.

(Saturation) We will say that a variable *x* of a given system - constrained to be in the compact set  $X \subset \mathbb{R}^{nx}$  - is saturated if it is in the boundary of *X*,  $\partial X$ , and this implies that the control objectives cannot be achieved.

(Saturation) We will say that a variable *x* of a given system - constrained to be in the compact set  $X \subset \mathbb{R}^{nx}$  - is saturated if it is in the boundary of *X*,  $\partial X$ , and this implies that the control objectives cannot be achieved.

If the control objective can be achieved, and to do that it necessary to keep the variable *x* in ∂*X*, then variable *x* is not saturated ⇒ it is a concept depending not only on the variable limits, but on the control objective.

(Saturation) We will say that a variable *x* of a given system - constrained to be in the compact set  $X \subset \mathbb{R}^{nx}$  - is saturated if it is in the boundary of *X*,  $\partial X$ , and this implies that the control objectives cannot be achieved.

- If the control objective can be achieved, and to do that it necessary to keep the variable *x* in ∂*X*, then variable *x* is not saturated ⇒ it is a concept depending not only on the variable limits, but on the control objective.
- We could have: transient saturation (associated to the velocity of the convergence, etc), or/and stationary saturation (when the target set or point is outside the feasible set)

(Saturation) We will say that a variable *x* of a given system - constrained to be in the compact set  $X \subset \mathbb{R}^{nx}$  - is saturated if it is in the boundary of *X*,  $\partial X$ , and this implies that the control objectives cannot be achieved.

- If the control objective can be achieved, and to do that it necessary to keep the variable *x* in ∂*X*, then variable *x* is not saturated ⇒ it is a concept depending not only on the variable limits, but on the control objective.
- We could have: transient saturation (associated to the velocity of the convergence, etc), or/and stationary saturation (when the target set or point is outside the feasible set)
- The concept of saturation is important in the context of Economic MPC since usually the control objective is to push the system to some limit, to maximize benefits and minimize costs.

• • = • • = •

Consider the following inverted pendulum:

State variables: position and velocity of the cart, and angular position and angular velocity of the pendulum

Controlled Output: position of the cart and angular position of the pendulum

Manipulated input: force applied to the cart. The force is subject to the following constraints:

$$\operatorname{sat}_{1}(u) = \begin{cases} 1 & \text{if } u > 1, \\ u & \text{if } |u| \le 1, \\ -1 & \text{if } u < -1, \end{cases}$$

< □ ▶ < 四▼

State variables: position and velocity of the cart, and angular position and angular velocity of the pendulum

Controlled Output: position of the cart and angular position of the pendulum

Manipulated input: force applied to the cart. The force is subject to the following constraints:

$$\operatorname{sat}_{1}(u) = \begin{cases} 1 & \text{if } u > 1, \\ u & \text{if } |u| \le 1, \\ -1 & \text{if } u < -1, \end{cases}$$

so the constrained system can be described by

$$\begin{aligned} x(k+1) &= Ax(k) + Bsat_1(u(k)) \\ y(k) &= Cx(k) \end{aligned}$$

< ロ > < 同 > < 回 > < 回 > < 回 >

State variables: position and velocity of the cart, and angular position and angular velocity of the pendulum

Controlled Output: position of the cart and angular position of the pendulum

Manipulated input: force applied to the cart. The force is subject to the following constraints:

$$\operatorname{sat}_{1}(u) = \begin{cases} 1 & \text{if } u > 1, \\ u & \text{if } |u| \le 1, \\ -1 & \text{if } u < -1, \end{cases}$$

so the constrained system can be described by

$$x(k+1) = Ax(k) + Bsat_1(u(k))$$
  
$$y(k) = Cx(k)$$

#### **Control Possibilities**

Next we will simulate a closed-loop (undefined control strategy by the moment) to see what can we do with this system.

< ロ > < 同 > < 回 > < 回 > < 回 >

• Assume an initial disturbance in the angular position ( $\theta(0) = 0.1$ ) to be rejected.

- Assume an initial disturbance in the angular position ( $\theta(0) = 0.1$ ) to be rejected.
- Solid line: aggressive controller; dashed line: more conservative controller.

- Assume an initial disturbance in the angular position ( $\theta(0) = 0.1$ ) to be rejected.
- Solid line: aggressive controller; dashed line: more conservative controller.

• Although the aggressive controller saturates the input at the first time instants, both controllers stabilize/control the closed-loop system.

• Output: **dashed-dotted line**. Unstable closed-loop behavior (formally, the disturbance steers the system outside the maximum controllable set).

- Output: **dashed-dotted line**. Unstable closed-loop behavior (formally, the disturbance steers the system outside the maximum controllable set).
- Conclusion: constraints affect the system controllability and stability

## How to deal with constraints

#### To get the most out of a system you need to push up against limits

According to Goodgwin et al. (2005), we have the following approaches:

#### Approaches to Constrained Control:

#### To get the most out of a system you need to push up against limits

According to Goodgwin et al. (2005), we have the following approaches:

• *Cautious*: back off performance demands so constraints are not met **drawback: poor performance**.

#### Approaches to Constrained Control:

#### To get the most out of a system you need to push up against limits

According to Goodgwin et al. (2005), we have the following approaches:

- *Cautious*: back off performance demands so constraints are not met **drawback: poor performance**.
- *Serendipitous*: allow occasional constraint violation **drawback**: saturation could occurs, and so unstable behavior

#### Approaches to Constrained Control:

#### To get the most out of a system you need to push up against limits

According to Goodgwin et al. (2005), we have the following approaches:

- *Cautious*: back off performance demands so constraints are not met **drawback: poor performance**.
- *Serendipitous*: allow occasional constraint violation **drawback**: saturation could occurs, and so unstable behavior
- *Tactical*: include constraints from the beginning, in the controller design (MPC). This way, any model representation includes not only the usual model parameters, but the corresponding variable limits.

Consider an objective function of the form:

$$V_N(x(0), \mathbf{u}) = \frac{1}{2} \sum_{k=0}^{N-1} (x(k)^T Q x(k) + u(k)^T R u(k)) + \frac{1}{2} x(N)^T P x(N)$$

where **u** denotes the control sequence  $\{u(0), u(1), ..., u(N-1)\}$  and x(k) denotes the corresponding state sequence. **u** and x(k) are related by the linear state equation (model):

$$x(k+1) = Ax(k) + Bu(k), \qquad k = 0, 1, ..., N-1$$

where x(0) (the initial state) is assumed to be known. The following parameters allow one to influence performance:

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Consider an objective function of the form:

$$V_N(x(0), \mathbf{u}) = \frac{1}{2} \sum_{k=0}^{N-1} (x(k)^T Q x(k) + u(k)^T R u(k)) + \frac{1}{2} x(N)^T P x(N)$$

where **u** denotes the control sequence  $\{u(0), u(1), ..., u(N-1)\}$  and x(k) denotes the corresponding state sequence. **u** and x(k) are related by the linear state equation (model):

$$x(k+1) = Ax(k) + Bu(k), \qquad k = 0, 1, ..., N-1$$

where x(0) (the initial state) is assumed to be known. The following parameters allow one to influence performance:

- the optimization horizon N
- the state weighting matrix Q
- the control weighting matrix R
- the terminal state weighting matrix *P*.

For example, reducing R gives less weight on control effort, hence faster response.

イロト 不得 とうほう イヨト

Consider the linear system:

 $\begin{aligned} x(k+1) &= Ax(k) + Bu(k) \\ y(k) &= Cx(k) \end{aligned}$ 

where 
$$A = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$$
,  $B = \begin{bmatrix} 0.5 \\ 1 \end{bmatrix}$   $y$   $C = \begin{bmatrix} 1 & 0 \end{bmatrix}$ 

Consider the linear system:

 $\begin{aligned} x(k+1) &= Ax(k) + Bu(k) \\ y(k) &= Cx(k) \end{aligned}$ 

where 
$$A = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$$
,  $B = \begin{bmatrix} 0.5 \\ 1 \end{bmatrix}$  y  $C = \begin{bmatrix} 1 & 0 \end{bmatrix}$ 

- This system is the zero-order hold discretisation with sampling period 1 of the double integrator:  $\frac{d^2y(t)}{dt^2} = u(t).$
- Manipulated input: force (acceleration and brake, depending of the sign)
- States: position and velocity of the mass, Initial state:  $x(0) = [-6 \ 0]^T$ ,
- Controlled output: position of the mass.

Consider the linear system:

 $\begin{aligned} x(k+1) &= Ax(k) + Bu(k) \\ y(k) &= Cx(k) \end{aligned}$ 

where 
$$A = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$$
,  $B = \begin{bmatrix} 0.5 \\ 1 \end{bmatrix}$   $y$   $C = \begin{bmatrix} 1 & 0 \end{bmatrix}$ 

- This system is the zero-order hold discretisation with sampling period 1 of the double integrator:  $\frac{d^2y(t)}{dt^2} = u(t).$
- Manipulated input: force (acceleration and brake, depending of the sign)
- States: position and velocity of the mass, Initial state:  $x(0) = [-6 \ 0]^T$ ,
- Controlled output: position of the mass.
- The physical constraints are given by  $|u(k)| \le 1$ , for all k, and they are modeled by the saturation function.

### **Cautious Design**

•  $(N = \infty, P = 0)$  and weighting matrices  $Q = C^T C = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$  and R = 20, gives the linear state feedback law:

$$u(k) = -Kx(k) = -[0.1603 \quad 0.5662]x(k).$$

### **Cautious Design**

•  $(N = \infty, P = 0)$  and weighting matrices  $Q = C^T C = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$  and R = 20, gives the linear state feedback law:

$$u(k) = -Kx(k) = -[0.1603 \quad 0.5662]x(k).$$

• With this control law, the limits are not reached by the input. However, a conservative performance is obtained.

### **Cautious Design**

Figure: u(k) and y(k) for the cautious design with weights  $Q = C^T C$  and R = 20.

Fundamentals of MPC

Bergamo, 20/06/2022 22/97

• Need a faster response? Reducing R = 2.

-

< 口 > < 同

• Need a faster response? Reducing R = 2.

Figure: Unconstrained LQR design u(k) = -Kx(k): dashed line. Serendipitous strategy,  $u(k) = -sat_1(Kx(k))$ : solid line.

< A

• Need a faster response? Reducing R = 2.

Figure: Unconstrained LQR design u(k) = -Kx(k): dashed line. Serendipitous strategy,  $u(k) = -\operatorname{sat}_1(Kx(k))$ : solid line.

• The input would saturate if constraints are present in the system.

• Need a faster response? Reducing R = 2.

Figure: Unconstrained LQR design u(k) = -Kx(k): dashed line. Serendipitous strategy,  $u(k) = -\operatorname{sat}_1(Kx(k))$ : solid line.

- The input would saturate if constraints are present in the system.
- Anyway, even with the saturation, the controller seems to work!

Antonio Ferramosca

• Let's "push our luck" further: R = 0.1 for an even faster response

• Let's "push our luck" further: R = 0.1 for an even faster response

Figure: Unconstrained LQR design u(k) = -Kx(k): dashed line. Serendipitous strategy,  $u(k) = -\operatorname{sat}_1(Kx(k))$ : solid line.

• Let's "push our luck" further: R = 0.1 for an even faster response

Figure: Unconstrained LQR design u(k) = -Kx(k): dashed line. Serendipitous strategy,  $u(k) = -\operatorname{sat}_1(Kx(k))$ : solid line.

• Unconstrained case: very fast response.

• Let's "push our luck" further: R = 0.1 for an even faster response

Figure: Unconstrained LQR design u(k) = -Kx(k): dashed line. Serendipitous strategy,  $u(k) = -\operatorname{sat}_1(Kx(k))$ : solid line.

• Saturated case (which represents reality): slower response (settling time of 12 samples).

• The control law  $u(k) = -\operatorname{sat}_1(Kx(k))$  partitions the state space into three regions in accordance with the definition of the sat function.

- The control law  $u(k) = -\operatorname{sat}_1(Kx(k))$  partitions the state space into three regions in accordance with the definition of the sat function.
- Hence, the serendipitous strategy can be characterized as a switched control strategy in the following way:

$$u = \kappa(x) = \begin{cases} -Kx & \text{if } x \in R_0, \\ 1 & \text{if } x \in R_1, \\ -1 & \text{if } x \in R_2. \end{cases}$$

- The control law  $u(k) = -\operatorname{sat}_1(Kx(k))$  partitions the state space into three regions in accordance with the definition of the sat function.
- Hence, the serendipitous strategy can be characterized as a switched control strategy in the following way:

$$u = \kappa(x) = \begin{cases} -Kx & \text{if } x \in R_0, \\ 1 & \text{if } x \in R_1, \\ -1 & \text{if } x \in R_2. \end{cases}$$

• Notice that this is simply an alternative way of describing the serendipitous strategy since for  $x \in R_0$  the input actually lies between the saturation limits. The partition is shown in following figure.

Antonio Ferramosca	Fundamentals of MPC	Bergamo, 20/06/2022	27/97

• Examination of the latter Figure suggests a heuristic argument as to why the serendipitous control law may not be performing well in this case.

Antonio Ferramosca	Fundamentals of MPC	Bergamo, 20/06/2022	28/97

イロト イポト イヨト イヨト

• We can think, in this example, of  $x_2(k)$  as "velocity" and  $x_1(k)$  as "position" of the mass.

Bergamo, 20/06/2022 29/97

• Now, in our attempt to change the position rapidly (from -6 a 0), the velocity has been allowed to grow to a relatively high level (+3). This would be fine if the braking action were unconstrained.

Antonio Ferramosca

Fundamentals of MPC

Bergamo, 20/06/2022

30/97

• However, our input (including braking) is limited to the range  $[-1 \ 1]$ . Hence, the available braking is inadequate to "pull the system up", and overshoot occurs.

Antonio Ferramosca

Bergamo, 20/06/2022 31/97

• Clearly, the problem with this strategy is that it does not know the constraint (variable limits), and so it cannot anticipate (predict) future saturations.

Antonio Ferramosca

Bergamo, 20/06/2022 32/97

• How could we remedy the problem?

- How could we remedy the problem?
- A sensible idea would seem to be to try to "look ahead" and take account of future input constraints (that is, the limited braking authority available).

- How could we remedy the problem?
- A sensible idea would seem to be to try to "look ahead" and take account of future input constraints (that is, the limited braking authority available).
- To test this idea, we take the objective function as a starting point.

- How could we remedy the problem?
- A sensible idea would seem to be to try to "look ahead" and take account of future input constraints (that is, the limited braking authority available).
- To test this idea, we take the objective function as a starting point.
- But we now design a finite horizon constrained controller.

• We use a prediction horizon N = 2 and minimize, at each sampling instant *i* and for the current state x(i), the two-step objective function:

• □ > • @ > • E > •

• We use a prediction horizon N = 2 and minimize, at each sampling instant *i* and for the current state x(i), the two-step objective function:

$$V_2(x(i), \mathbf{u}) = \frac{1}{2} \sum_{k=i}^{i+1} (x(k)^T Q x(k) + u(k)^T R u(k)) + \frac{1}{2} x(i+2)^T P x(i+2)$$

• □ > • @ > • E > •

• We use a prediction horizon N = 2 and minimize, at each sampling instant *i* and for the current state x(i), the two-step objective function:

$$V_2(x(i), \mathbf{u}) = \frac{1}{2} \sum_{k=i}^{i+1} (x(k)^T Q x(k) + u(k)^T R u(k)) + \frac{1}{2} x(i+2)^T P x(i+2)$$

subject to the equality and inequality constraints:

$$\begin{aligned} x(k+1) &= Ax(k) + Bu(k), \\ |u(k)| &\leq 1, \end{aligned}$$

for k = i and k = i + 1.

• We use a prediction horizon N = 2 and minimize, at each sampling instant *i* and for the current state x(i), the two-step objective function:

$$V_2(x(i), \mathbf{u}) = \frac{1}{2} \sum_{k=i}^{i+1} (x(k)^T Q x(k) + u(k)^T R u(k)) + \frac{1}{2} x(i+2)^T P x(i+2)$$

subject to the equality and inequality constraints:

$$\begin{aligned} x(k+1) &= Ax(k) + Bu(k), \\ |u(k)| &\leq 1, \end{aligned}$$

for k = i and k = i + 1.

• In the objective function we set, as before,  $Q = C^T C$ , R = 0.1.

• • • • • • • • • • • • •

• We use a prediction horizon N = 2 and minimize, at each sampling instant *i* and for the current state x(i), the two-step objective function:

$$V_2(x(i), \mathbf{u}) = \frac{1}{2} \sum_{k=i}^{i+1} (x(k)^T Q x(k) + u(k)^T R u(k)) + \frac{1}{2} x(i+2)^T P x(i+2)$$

subject to the equality and inequality constraints:

$$\begin{aligned} x(k+1) &= Ax(k) + Bu(k), \\ |u(k)| &\leq 1, \end{aligned}$$

for k = i and k = i + 1.

- In the objective function we set, as before,  $Q = C^T C$ , R = 0.1.
- The terminal state weighting matrix *P* is taken to be the solution of the Riccati equation  $P = A^T P A + Q - K^T (R + B^T P B) K$ , where  $K = (R + B^T P B)^{-1} B^T P A$  is the corresponding gain (state feedback).

イロト イポト イラト イラト

• As a result of minimizing the cost function subject to the constraints, we obtain an optimal fixed-horizon control sequence  $\{u(i), u(i+1)\}$ .

- As a result of minimizing the cost function subject to the constraints, we obtain an optimal fixed-horizon control sequence  $\{u(i), u(i+1)\}$ .
- We then apply the resulting value of u(i) to the system. The state evolves to x(i+1); the time instant is shifted from *i* to i+1, and the procedure is repeated.

- As a result of minimizing the cost function subject to the constraints, we obtain an optimal fixed-horizon control sequence  $\{u(i), u(i+1)\}$ .
- We then apply the resulting value of u(i) to the system. The state evolves to x(i+1); the time instant is shifted from *i* to i+1, and the procedure is repeated.
- This is called **receding horizon control** [RHC] or model predictive control.

• The output trajectory with constrained input now has minimal overshoot and fast response. Thus, the idea of "looking ahead" and applying the constraints in a receding horizon fashion has apparently "paid dividends."

Figure: State space plot for the receding horizon tactical design and serendipitous design, respectively

### Conclusion about Constraints

#### • One can often avoid constraints by lowering performance demands

### Conclusion about Constraints

- One can often avoid constraints by lowering performance demands
- However, this is at a cost

### Conclusion about Constraints

- One can often avoid constraints by lowering performance demands
- However, this is at a cost
- If we increase demands constraints are met

- One can often avoid constraints by lowering performance demands
- However, this is at a cost
- If we increase demands constraints are met
- Small violations not too significant

- One can often avoid constraints by lowering performance demands
- However, this is at a cost
- If we increase demands constraints are met
- Small violations not too significant
- Large violations  $\rightarrow$  poor performance

- One can often avoid constraints by lowering performance demands
- However, this is at a cost
- If we increase demands constraints are met
- Small violations not too significant
- Large violations  $\rightarrow$  poor performance
- Rethink the problem add constraints into the design

- One can often avoid constraints by lowering performance demands
- However, this is at a cost
- If we increase demands constraints are met
- Small violations not too significant
- Large violations  $\rightarrow$  poor performance
- Rethink the problem add constraints into the design
- This leads to idea of Receding Horizon Control (**Optimizing Control**): RHC can anticipate the presence of constraints thus achieving a better control.

• Use a dynamical model of the process (including constraints)

$$x(k+1) = f(x(k), u(k)), \quad x(k) \in \mathcal{X}, u(k) \in \mathcal{U}$$

• to predict its future evolution by choosing the best control sequence

$$\mathbf{u} = \{u(k), u(k+1), \dots, u(k+N-1)\}$$

• that minimizes the performance index:

$$V_N(x; \mathbf{u}) = \sum_{j=0}^{N-1} (\|x(k+j)\|_Q^2 + \|u(k+j)\|_R^2)$$

 $Q \ge 0, R > 0$ . Prediction horizon:  $N \ge 1$ .

Open-loop solution: minimize the performance index with respect to the control sequence **u**.

# **Receding Horizon Principle**

Open-loop solution: minimize the performance index with respect to the control sequence **u**. How do we close the loop?  $\rightarrow$  Receding Horizon Principle

### Definition (Receding Horizon Principle)

"at any time k solve the OCP over the prediction horizon [k,k+N] and apply only the first input  $u^0(k)$  of the optimal sequence  $\mathbf{u}^0(k)$ . At time k+1, move the prediction window one step ahead, and repeat the optimization over the prediction horizon [k+1,k+N+1]"

# **Receding Horizon**

• At time *k*, solve an optimal control problem (OCP) over a future horizon of N steps

$$\min_{\mathbf{u}} \sum_{j=0}^{N-1} (\|x(j) - x_{sp}\|_{Q}^{2} + \|u(j) - u_{sp}\|_{R}^{2})$$
s.t.  $x(0) = x(k)$   
 $x(j+1) = f(x(j), u(j))$   
 $x(j) \in \mathcal{X}, u(j) \in \mathcal{U}, j \in \mathbb{I}_{[0,N-1]}$ 

< ロ > < 同 > < 回 > < 回 > < 回 >

- Apply the first control move *u*(*k*).
- At time k + 1, get new measurement and solve the OCP. And so on...

MPC transforms open-loop control into closed-loop control.

# **Receding Horizon Examples**

• Playing chess.

#### • Driving.

Fundamentals of MPC

5900

44/97

### MPC with linear systems

• Dynamical model of the form

 $x(k+1) = Ax(k) + Bu(k), \quad x(k) \in \mathcal{X}, \ u(k) \in \mathcal{U}$ 

< A

### MPC with linear systems

• Dynamical model of the form

$$x(k+1) = Ax(k) + Bu(k), \quad x(k) \in \mathcal{X}, \ u(k) \in \mathcal{U}$$

• then the OCP

$$\min_{\mathbf{u}} \sum_{j=0}^{N-1} (\|x(j) - x_{sp}\|_{Q}^{2} + \|u(j) - u_{sp}\|_{R}^{2})$$
s.t.  $x(0) = x(k), \quad x(j+1) = Ax(j) + Bu(j)$ 
 $x(j) \in \mathcal{X}, \ u(j) \in \mathcal{U}, \ j \in \mathbb{I}_{[0,N-1]}$ 

is a convex Quadratic Programming (QP) problem (Boyd & Vandenberghe, 2006)

$$\min_{\mathbf{u}} \quad \frac{1}{2}\mathbf{u}'H\mathbf{u} + f'\mathbf{u} + r$$
  
s.t.  $G\mathbf{u} \le W$ 

Widely used in the process industries Camacho & Bordons (2004)

• Usually in its "original" Dynamic Matrix Control (DMC) formulation (AspenTech, Honeywll, ABB).

#### Linear vector space

A linear vector space, or simply vector space (real or complex) is a set  $\mathcal{X}$  where two operations are defined  $+: \mathcal{X} \times \mathcal{X} \to \mathcal{X}$ , called sum, and  $\bullet: \mathbb{R} \times \mathcal{X} \to \mathcal{X}$  (or  $\bullet: \mathbb{C} \times \mathcal{X} \to \mathcal{X}$ ), called scalar product, such that the following axioms are verified:

- $x + y = y + x, \quad \forall x, y \in \mathcal{X} \text{ (commutativity of the sum)}$
- 2  $x + (y + z) = (y + x) + z, \quad \forall x, y, z \in \mathcal{X}$  (associativity of the sum)
- (a) there exists an element  $0 \in \mathcal{X}$  s. t. 0 + x = x + 0 = x,  $\forall x \in \mathcal{X}$  (existence of the **neutral** element w.r.t. the sum)

(a) for all  $x \in \mathcal{X}$  there exists an element  $-x \in \mathcal{X}$  s. t. x + (-x) = 0 (existence of the **inverse** element w.r.t. the sum)

(a) for all  $r_1, r_2 \in \mathbb{R}$   $(c_1, c_2 \in \mathbb{C})$ , and each  $x \in \mathcal{X}$ , there exists an element  $r_1 \cdot (r_2 \cdot x) = (r_1 r_2) \cdot x$  $(c_1 \cdot (c_2 \cdot x) = (c_1 c_2) \cdot x)$ 

• for all  $r \in \mathbb{R}$  ( $c \in \mathbb{C}$ ), and each  $x, y \in \mathcal{X}$ , there exists an element  $r \cdot (x + y) = r \cdot x + r \cdot y$ ( $c \cdot (x + y) = c \cdot x + c \cdot y$ )

- (a) for all  $r_1, r_2 \in \mathbb{R}$   $(c_1, c_2 \in \mathbb{C})$ , and each  $x \in \mathcal{X}$ , there exists an element  $(r_1 + r_2) \cdot x = r_1 \cdot x + r_2 \cdot x ((c_1 + c_2) \cdot x = c_1 \cdot x + c_2 \cdot x)$
- So for all  $x \in \mathcal{X}$ ,  $1 \cdot x = x$ .

- $||x + y|| \le ||x|| + ||y||, \text{ for all } x, y \in \mathcal{X} \text{ (triangle inequality).}$

### Remark

Note that the concept of norm in a normed vector space is a generalization of the concept of distance in  $\mathbb{R}^2$ .  $\mathbb{R}^3$ . Then, ||x - y|| can be seen as the distance between the two vectors or elements x and y. This concept allows us to define the notions of convergence and proximity in a vector space.

### Examples of norm oeprators

In general a *p*-norm in  $\mathbb{R}^n$  is defined as:

$$||x||_p = \sqrt[p]{|x_1|^p + |x_2|^p + \dots + |x_n|^p}$$

We can now define the concepts of *convergence* and *continuity* in a vector space.

We can now define the concepts of convergence and continuity in a vector space.

#### Convergence

Let  $\{x_n\}_{1}^{\infty}$  be a sequence of elements belonging to a normed vector space  $(\mathcal{X}, \|\cdot\|)$ . We say that such a sequence *converges* to the element  $x_0 \in \mathcal{X}$  if  $\|x_n - x_0\| \to 0$  for  $n \to \infty$ .

• • = • • = •

< □ ▶ < 四▼

We can now define the concepts of convergence and continuity in a vector space.

#### Convergence

Let  $\{x_n\}_1^\infty$  be a sequence of elements belonging to a normed vector space  $(\mathcal{X}, \|\cdot\|)$ . We say that such a sequence *converges* to the element  $x_0 \in \mathcal{X}$  if  $\|x_n - x_0\| \to 0$  for  $n \to \infty$ . That is,  $\{x_n\}_1^\infty$  *converges* to  $x_0$  if, for all  $\epsilon > 0$ , there exists and integer  $N(\epsilon)$  such that

 $||x_n - x_0|| < \epsilon$ , for all  $n \ge N(\epsilon)$ .

We can now define the concepts of convergence and continuity in a vector space.

#### Convergence

Let  $\{x_n\}_1^\infty$  be a sequence of elements belonging to a normed vector space  $(\mathcal{X}, \|\cdot\|)$ . We say that such a sequence *converges* to the element  $x_0 \in \mathcal{X}$  if  $\|x_n - x_0\| \to 0$  for  $n \to \infty$ . That is,  $\{x_n\}_1^\infty$  *converges* to  $x_0$  if, for all  $\epsilon > 0$ , there exists and integer  $N(\epsilon)$  such that

 $||x_n - x_0|| < \epsilon$ , for all  $n \ge N(\epsilon)$ .

#### Remark

We can give different interpretations to the previous definition:

•  $\{x_n\}_1^\infty \to x_0 \text{ iff the sequence } \{\|x_n - x_0\|\}_1^\infty \to 0.$ 

イロト イポト イヨト イヨト 二日

# Counter example: continuous, but not uniformly, functi

Function  $f(x) = \frac{1}{x}$  is not uniformly continuous in  $[0, \infty)$ . It is however uniformly continuous in any interval  $[a, \infty)$ , with a > 0.

Very close to the previous concepts, there's the concept of Lipschitz continuity.

#### Lipschitz continuity

Let  $(\mathcal{X}, \|\cdot\|_{\mathcal{X}})$  and  $(\mathcal{Y}, \|\cdot\|_{\mathcal{Y}})$  be two normed vector spaces. Let f be a *mapping* from  $\mathcal{X}$  to  $\mathcal{Y}$ . We state that f is *Lipschitz continuous in*  $\mathcal{S} \subseteq \mathcal{X}$  if there exists a real constant  $L \ge 0$  such that

 $||f(x_1) - f(x_2)||_{\mathcal{Y}} \le L ||x_1 - x_2||_{\mathcal{X}}$  for all  $x_1, x_2 \in S$ .

(4 個) トイヨ ト イヨ トー

Very close to the previous concepts, there's the concept of Lipschitz continuity.

#### Lipschitz continuity

Let  $(\mathcal{X}, \|\cdot\|_{\mathcal{X}})$  and  $(\mathcal{Y}, \|\cdot\|_{\mathcal{Y}})$  be two normed vector spaces. Let f be a mapping from  $\mathcal{X}$  to  $\mathcal{Y}$ . We state that f is *Lipschitz continuous in*  $\mathcal{S} \subseteq \mathcal{X}$  if there exists a real constant  $L \ge 0$  such that

$$||f(x_1) - f(x_2)||_{\mathcal{V}} \le L ||x_1 - x_2||_{\mathcal{X}}$$
 for all  $x_1, x_2 \in S$ .

#### Theorem

Lipschitz continuous function are uniformly continuous.

• • = • • = •

Very close to the previous concepts, there's the concept of Lipschitz continuity.

#### Lipschitz continuity

Let  $(\mathcal{X}, \|\cdot\|_{\mathcal{X}})$  and  $(\mathcal{Y}, \|\cdot\|_{\mathcal{Y}})$  be two normed vector spaces. Let f be a mapping from  $\mathcal{X}$  to  $\mathcal{Y}$ . We state that f is *Lipschitz continuous in*  $\mathcal{S} \subseteq \mathcal{X}$  if there exists a real constant  $L \ge 0$  such that

$$||f(x_1) - f(x_2)||_{\mathcal{V}} \le L ||x_1 - x_2||_{\mathcal{X}}$$
 for all  $x_1, x_2 \in S$ .

#### Theorem

Lipschitz continuous function are uniformly continuous.

#### Remark

Let's suppose that  $f : \mathbb{R} \to \mathbb{R}$ . Due to the mean value theorem, if f is differentiable in  $[x_1, x_2]$ , then

$$|f(x_1) - f(x_2)| \le f'(c) |x_1 - x_2|$$
 for some  $c \in [x_1, x_2]$ .

Therefore, if  $x_1 y x_2$  belong to an interval S and  $f'(c) \le L$ , for all  $c \in S$ , then it follows that f is Lipschitz continuous.

Antonio Ferramosca	Fundamentals of MPC	Bergamo, 20/06/2022	56/97

#### Closed set

A set  $S \in \mathcal{X}$  is *closed* iff all converging sequences, with elements in *S*, have limit in *S*.

#### Closed set

A set  $S \in \mathcal{X}$  is *closed* iff all converging sequences, with elements in *S*, have limit in *S*.

#### Remark

Different definitions (i) A closed set can be defined as a set which contains all its limit points.

(ii) A set is closed if its complement is an open set.

(iii) Roughly speaking, a set is closed if it contains its boundary.

#### Closed set

A set  $S \in \mathcal{X}$  is *closed* iff all converging sequences, with elements in *S*, have limit in *S*.

#### Remark

Different definitions (i) A closed set can be defined as a set which contains all its limit points.

(ii) A set is closed if its complement is an open set.

(iii) Roughly speaking, a set is closed if it contains its boundary.

#### Bounded set

A set  $S \in \mathcal{X}$  is *bounded* if it is in some sense of finite size.

- The interval  $A = (-\infty, -2]$  is not compact because it is not bounded.
- The interval C = (2, 4) is not compact because it is not closed.
- The interval B = [0, 1] is compact because it is both bounded and closed.

< □ > < 同

A sequence  $\{x_n\}_1^\infty$  in a normed vector space  $(\mathcal{X}, \|\cdot\|)$  converges to  $x_0$  if  $\|x_n - x_0\|$  tends to zero when  $n \to \infty$ .

However, in many cases the limit point of a certain sequence is unknown. This is the case for instance, of iterative solutions to differential equations.

We then need a different way to characterize a sequence, which does not depend on the (unknown) limit point if such a sequence. We introduce the concept of Cauchy sequence.

We then need a different way to characterize a sequence, which does not depend on the (unknown) limit point if such a sequence. We introduce the concept of Cauchy sequence.

#### Cauchy sequence

Let  $\{x_n\}_1^\infty$  be a sequence of elements belonging to a normed vector space  $(\mathcal{X}, \|\cdot\|)$ . We say that such a sequence is a *Cauchy sequence* if, for all  $\epsilon > 0$ , there exists an integer  $N(\epsilon)$  such that

 $||x_n - x_m|| < \epsilon$ , for all  $n, m \ge N(\epsilon)$ .

イロト 不得 とくき とくき とうき

A sequence  $\{x_n\}_1^\infty$  in a normed vector space  $(\mathcal{X}, \|\cdot\|)$  converges to  $x_0$  if  $\|x_n - x_0\|$  tends to zero when  $n \to \infty$ .

 $||x_n - x_m|| < \epsilon$ , for all  $n, m \ge N(\epsilon)$ .

#### Remark

Based on the above definition, a sequence  $\{x_n\}_{1}^{\infty}$  is convergent if its terms  $x_n$  get arbitrarily closer to a fixed element  $x_0$ . On the other hand, it will be a Cauchy sequence if its terms get arbitrarily closer to each other, when  $n \to \infty$ .

# Lyapunov Stability Theory

• Lyapunov theory is the mathematical extension of a physical observation: if a physical system dissipates mechanical energy, then it eventually settles down to an equilibrium point.

< □ > < 同

- Lyapunov theory is the mathematical extension of a physical observation: if a physical system dissipates mechanical energy, then it eventually settles down to an equilibrium point.
- Consider the mass-spring-damper system

- Lyapunov theory is the mathematical extension of a physical observation: if a physical system dissipates mechanical energy, then it eventually settles down to an equilibrium point.
- Consider the mass-spring-damper system

• Dynamic equation

 $m\ddot{x} + c\dot{x} + kx = 0$ 

• Total mechanical energy = kinetic energy + potential energy

$$V(x) = \frac{1}{2}m\dot{x}^{2} + \int_{0}^{x} (kx)dx = \frac{1}{2}m\dot{x}^{2} + \frac{1}{2}kx^{2}$$

• • • • • • • • • • • • •

Э

• Total mechanical energy = kinetic energy + potential energy

$$V(x) = \frac{1}{2}m\dot{x}^{2} + \int_{0}^{x} (kx)dx = \frac{1}{2}m\dot{x}^{2} + \frac{1}{2}kx^{2}$$

- Zero energy corresponds to the equilibrium  $(x = 0, \dot{x} = 0)$ .
- Asymptotic stability implies that energy converges to zero.
- Instability is related to the growth of mechanical energy.

• Total mechanical energy = kinetic energy + potential energy

$$V(x) = \frac{1}{2}m\dot{x}^{2} + \int_{0}^{x} (kx)dx = \frac{1}{2}m\dot{x}^{2} + \frac{1}{2}kx^{2}$$

- Zero energy corresponds to the equilibrium  $(x = 0, \dot{x} = 0)$ .
- Asymptotic stability implies that energy converges to zero.
- Instability is related to the growth of mechanical energy.
- Rate of energy during system's motion:

$$\dot{V}(x) = m\ddot{x}\dot{x} + kx\dot{x} = (-c\dot{x})\dot{x}$$
$$= -c\dot{x}^{2}$$

• Rate of energy during system's motion:  $\dot{V}(x) = -c\dot{x}^2$ 

- Rate of energy during system's motion:  $\dot{V}(x) = -c\dot{x}^2$
- c > 0 implies that the energy of the system is continuously dissipated by the damper until the mass settles down ( $\dot{x} = 0$ ): AS.

- Rate of energy during system's motion:  $\dot{V}(x) = -c\dot{x}^2$
- c > 0 implies that the energy of the system is continuously dissipated by the damper until the mass settles down ( $\dot{x} = 0$ ): AS.
- c = 0 implies that the energy of the system does not dissipate or grow. We have harmonic oscillations: only stability for bounded initial conditions.

- Rate of energy during system's motion:  $\dot{V}(x) = -c\dot{x}^2$
- c > 0 implies that the energy of the system is continuously dissipated by the damper until the mass settles down ( $\dot{x} = 0$ ): AS.
- c = 0 implies that the energy of the system does not dissipate or grow. We have harmonic oscillations: only stability for bounded initial conditions.
- *c* < 0 implies that the energy of the system grows and the mass never settles down: instability.

## Support functions

Consider the following definitions:

Э

## Support functions

Consider the following definitions:

#### Function $\mathcal{K}$

A function  $\alpha : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$  is a  $\mathcal{K}$ -function if:

- it is continuous.
- it is strictly increasing, i.e., if a > b, then  $\alpha(a) > \alpha(b)$ .

• 
$$\alpha(0) = 0.$$

A function  $\alpha : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$  is a  $\mathcal{K}_{\infty}$ -function if it is a  $\mathcal{K}$ -function and

• 
$$\alpha(a) \to \infty$$
 when  $a \to \infty$  (unbounded).

A function  $\beta : \mathbb{R}_{\geq 0} \times \mathbb{I}_{\geq 0} \to \mathbb{R}_{\geq 0}$  is a  $\mathcal{KL}$ -function of:

- the function  $\beta(a, k)$  is  $\mathcal{K}$  in *a* for every fixed  $k \ge 0$ .
- the function β(a, k) is nonincreasing in k for every fixed a ≥ 0, in such a way that β(a, k) → 0 for k → ∞.

## ${\mathcal K} \text{ and } {\mathcal K}_\infty\text{-functions}$

Fundamentals of MPC

Bergamo, 20/06/2022 74/97

イロト イポト イヨト イヨト

## Example of ${\mathcal K}$ -function

Consider the function

$$\alpha(r) = tan^{-1}(r)$$

• It is strictly increasing as

$$\frac{d\alpha(r)}{dr}=\frac{1}{(1+r)^2}>0$$

• 
$$\alpha(0) = 0$$

• 
$$\lim_{r\to\infty} \alpha(r) = \frac{\pi}{2}$$

It's a  ${\mathcal K}$  -function.

## Example of $\mathcal{K}_\infty$ -function

#### Consider the function

$$\alpha(r) = r^c$$

for any c > 0

• It is strictly increasing as

$$\frac{d\alpha(r)}{dr} = cr^{c-1} > 0$$

• 
$$\alpha(0) = 0$$

• 
$$\lim_{r\to\infty} \alpha(r) = \infty$$

It's a  $\mathcal{K}_\infty$  -function.

## Example of $\mathcal{KL}$ -function

Consider the function

$$\beta(r,s) = \frac{r}{(krs+1)}, \quad k > 0$$

• It is strictly increasing in *r*:

$$\frac{\partial \beta(r,s)}{\partial r} = \frac{1}{(krs+1)^2} > 0$$

• It is strictly decreasing in *s*:

$$\frac{\partial \beta(r,s)}{\partial s} = \frac{-kr^2}{(krs+1)^2} < 0$$

 $\bullet \ \beta(0,0)=0$ 

• 
$$\beta(r,s) \to 0$$
 as  $s \to \infty$ 

It's a  $\mathcal{KL}$  -function.

## Properties of ${\mathcal K}$ and ${\mathcal K}_\infty\text{-functions}$

#### Properties of $\mathcal{K}$ and $\mathcal{K}_{\infty}$ -functions

Let  $\alpha_1(\cdot)$  and  $\alpha_2(\cdot)$  be  $\mathcal{K}$ -functions ( $\mathcal{K}_{\infty}$ -functions), then

•  $\alpha_i^{-1}(\cdot)$  defines the inverse function of  $\alpha_i(\cdot)$  and it is defined in  $[0, \mathbb{R})$ .

## Properties of ${\mathcal K}$ and ${\mathcal K}_\infty\text{-functions}$

#### Properties of ${\mathcal K}$ and ${\mathcal K}_\infty\text{-functions}$

## Lyapunov Stability Theory

#### Definition (Lyapunov function)

A function  $V : \mathbb{R}^{nx} \to \mathbb{R}_{\geq 0}$  is said to be a Lyapunov function for the system  $x^+ = f(x)$  and set  $\Omega$  if there exist  $\mathcal{K}_{\infty}$ -functions  $\alpha_1$  y  $\alpha_2$ , and a  $\mathcal{PD}$  function  $\alpha_3$ , such that for any  $x \in \mathbb{R}^{nx}$ ,

$$\begin{array}{rcl} V(x) & \geq & \alpha_1(|x|_{\Omega}), \\ V(x) & \leq & \alpha_2(|x|_{\Omega}), \\ V(f(x)) - V(x) & \leq & -\alpha_3(|x|_{\Omega}), \end{array}$$

## Lyapunov Stability Theory

The existence of a Lyapunov function is a sufficient condition for (global) asymptotic stability as shown in the next result which can be proved under the assumption, common in MPC, that  $\alpha_3(\cdot)$  is  $\mathcal{K}_{\infty}$ .

#### Theorem (Lyapunov function and GAS)

Suppose  $V(\cdot)$  is a Lyapunov function for  $x^+ = f(x)$  and set  $\Omega$ , with  $\alpha_3(\cdot)$  a  $\mathcal{K}_{\infty}$ -function. Then  $\Omega$  is globally asymptotically stable.

A detailed proof can be found in (Rawlings & Mayne, 2009, Appendix B, Theorem B.11, pag. 609)

A B M A B M

• Suppose x is the initial state, and  $|x|_{\Omega} < \delta$ .

프 > < 프 >

• From the second condition,  $V(x) \le \alpha_2(|x|_{\Omega})$ , then  $V(x) \le \alpha_2(\delta) = \alpha_1(\epsilon)$ .

• • = • • = •

• From  $V(f(x)) - V(x) \le -\alpha_3(|x|_{\Omega})$ , then  $\{V(x(i)) : i \in \mathbb{I}_{\ge 0}\}$ , with  $x(i) \triangleq \phi(i; x)$ , is a nonincreasing sequence.

A B > A B >

• So, for all  $i \in \mathbb{I}_{\geq 0}$   $V(x(i)) \leq V(x)$ , where x is the initial state.

A B M A B M

• From  $V(x) \ge \alpha_1(|x|_{\Omega})$ , then  $\alpha_1(|x(i)|_{\Omega}) \le V(x(i)) \le V(x)$ . Recall that  $V(x) \le \alpha_2(\delta) = \alpha_1(\epsilon)$ .

• • = • • = •

• Then  $|x(i)|_{\Omega} \leq \alpha_1^{-1}(V(x)) \leq \alpha_1^{-1}(\alpha_1(\epsilon)) = \epsilon$ , for any  $|x|_{\Omega} \leq \delta$ 

• • = • • = •

• Let  $x \in \mathbb{R}^{nx}$  be arbitrary. From the second Lyapunov function condition V(x) is finite, and from the first and third condition,  $\{V(x(i)) : i \in \mathbb{I}_{\geq 0}\}$ , with  $x(i) \stackrel{\Delta}{=} \phi(i; x)$ , is nonincreasing and bounded from below by zero.

• Hence both, V(x(i)) and V(x(i+1)) converge to a  $\overline{V} \ge 0$ , as  $i \to \infty$  (prop. of real sequences).

• Since  $[V(x(i+1)) - V(x(i))] \to 0$  as  $i \to \infty$  and x(i+1) = f(x(i)) then from the third condition  $\alpha_3(|x(i)|_{\Omega}) \to 0$  as  $i \to \infty$ .

• Since  $|x(i)|_{\Omega} = \alpha_3^{-1}(\alpha_3(|x(i)|_{\Omega}))$ , where  $\alpha_3^{-1}$  is a  $\mathcal{K}_{\infty}$ -function, then  $|x(i)|_{\Omega} \to 0$  as  $i \to \infty$ .

• We use Lyapunov stability theory.
